Problem Statement: Abalone Age Prediction

Description :

Predicting the age of abalone from physical measurements. The age of abalone is determined by cutting the shell through the cone, staining it, and counting the number of rings through a microscope -- a boring and time-consuming task. Other measurements, which are easier to obtain, are used to predict age. Further information, such as weather patterns and location (hence food availability) may be required to solve the problem.

Importing Modules

In [1]:

```
import pandas as pd
import seaborn as sns
import matplotlib.pyplot as plt
import numpy as np
```

1. Dataset has been downloaded

In [ ]:

```
#Name of the dataset: abalone.csv
```

2. Load the dataset into the tool

In[12]:

```
data=pd.read_csv("abalone.csv")
data.head()
```

Out[12]:

	Sex	Length	Diameter	Height	Whole weight	Shucked weight	Viscera weight	Shell weight	Rings

4	I	0.330	0.255	0.080	0.2050	0.0895	0.0395	0.055	7

Let's know the shape of the data

In [13]:

```
data.shape
```

Out[13]:

```
(4177, 9)
```

One additional task is that, we have to add the "Age" column using "Rings" data. We just have to add '1.5' to the ring data

In [14]:

```
Age=1.5+data.Rings
data["Age"]=Age
data=data.rename(columns = {'Whole weight':'Whole_weight','Shucked weight': 'Shucked_weight','Viscera weight': 'Viscera_weight',
                              'Shell weight': 'Shell_weight'})
data=data.drop(columns=["Rings"],axis=1)
data.head()
```

Out[14]:

	Sex	Length	Diameter	Height	Whole_weight	Shucked_weight	Viscera_weight	Shell_weight	Age
0	M	0.455	0.365	0.095	0.5140	0.2245	0.1010	0.150	16.5

3. Perform Below Visualizations.

(i) Univariate Analysis

# #

The term univariate analysis refers to the analysis of one variable. You can remember this because the prefix “uni” means “one.” There are three common ways to perform univariate analysis on one variable: 1. Summary statistics – Measures the center and spread of values.

Histogram

sns.displot(data["Age"], color='darkorange')
```

```

In[106]:

```
sns.histplot(x=data.Age,color='green')

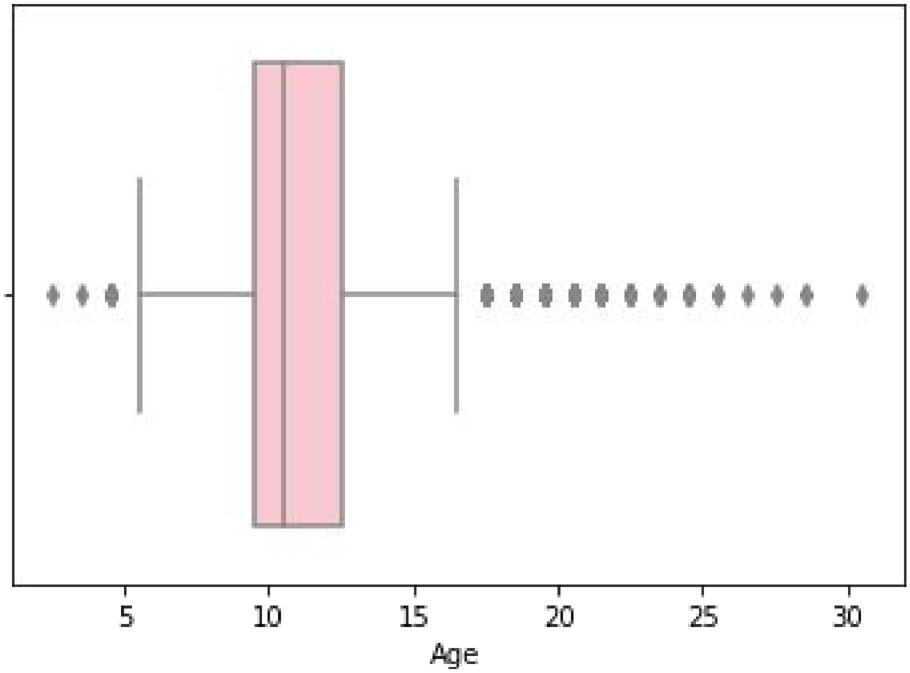
<AxesSubplot:xlabel='Age'>



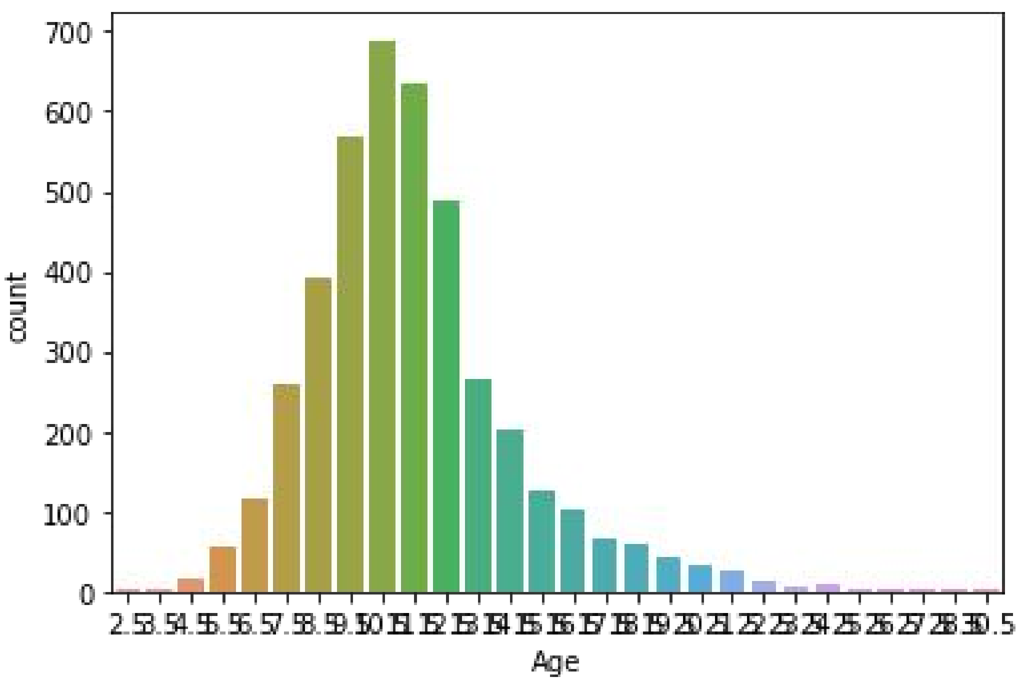
Countplot

In [51]:

```
sns.countplot(x=data.Age)
```

Out[51]:

<AxesSubplot:xlabel='Age', ylabel='count'>



(ii) Bi-Variate Analysis

# #

Image result for bivariate analysis in python It is a methodical statistical technique applied to a pair of variables (features/ attributes) of data to determine the empirical relationship between them. In order words, it is meant to determine any concurrent relations (usually over and above a simple correlation analysis).

# #

Barplot

In [50]:

```
sns.barplot(x=data.Height,y=data.Age)
```

Out[50]:

```
<AxesSubplot:xlabel='Height', ylabel='Age'>

```

Out[42]:

```

```

Out[48]:

```
<AxesSubplot:xlabel='Age', ylabel='Height'>

(iii) Multi-Variate Analysis

#

Multivariate analysis is based in observation and analysis of more than one statistical outcome variable at a time. In design and analysis, the technique is used to perform trade studies across multiple dimensions while taking into account the effects of all variables on the responses of interest.

#

Pairplot

In [57]:

```
sns.pairplot(data=data[["Height","Length","Diameter","Age","Whole_weight","Sh
ucked_weight","Viscera_weight","Shell_weight"]])
```

```
